

My Travel Agency Project is named Agencia Flor de Maga. The hypothetical agency is based in Puerto Rico and started by a family, the Romanos. The Agency website features a Home page (home.html and home.php), Booking page (bookingform.php and processbooking.php), Contact page (contact.php), About Us page (aboutus.php), a bonus About Company Logo page (aboutlogo.php), and lastly, an Our Services dropdown box. The Service dropdown box holds Stays, Activities, and Food pages (stays.php, food.php, and activities.php). Each of these pages hold all the information of the associated packages for the guest to pick from. The majority of these pages are more text based except from the Booking page (bookingform.php and processbooking.php). The home page(s) simply introduces the company to the user, the things they offer, and encourages them to search the website. The stays page tells the user about the selections the company is offering and the price range per night. The page also displays pictures of the stays. The activities page tells the user the exclusive activities the company is offering and the price range. The price range is fixed for the entirety of the trip. The food page tells the user of the food packages that the company offers to go along with the stay packages. The price range is fixed for the entirety of the trip. The Booking Page tells the user about the guidelines for the booking and how they should input information into the booking form. The contact page simply states the company contact info. The About Us page gives the company backstory of when they started and why they wanted to start the company. There is also a hint to the bonus page. The About Logo page simply gives info on the origin of the logo. Some features that were added included linking the home page (home.php) to the company name at the top left and the bonus company logo page to flower at the top left. The booking table also has the Stays, Activities, and Food page link to the word on the table. This helps the user go back to those pages quicker than going back up to the dropdown box. The project has similarities to the Homework One, which

utilized the orderform.html and processorder.php. Also, Homework Two, which utilized the header. The table was necessary in processing the order for the booking and the header helped transfer the code for each page. The processing form allows a \$50 discount for new users, otherwise the calculations are made and the total with and without tax is displayed along with the other info. I utilized if...else and if...elseif to achieve this. Also, the use of break (
) and non-break space () helped to achieve the format of the output. One of the major challenges in doing this project included the use of CSS. Mostly because I am not acquainted with it. With the help of Youtube, practice, and refining the code until the display was to my personal preference, it worked out. The CSS style page is used for the header, body, and navigation bar. In addition, the booking table, the design of the stays page, and the flower picture positioning on the bonus page. Also, utilized class names (class = "namehere") to help identify the set of code I was editing with CSS styling. In the end, the display came out as desired. Overall, the Agencia Flor de Maga project provided a good challenge to work on the material and learn something else as well.
